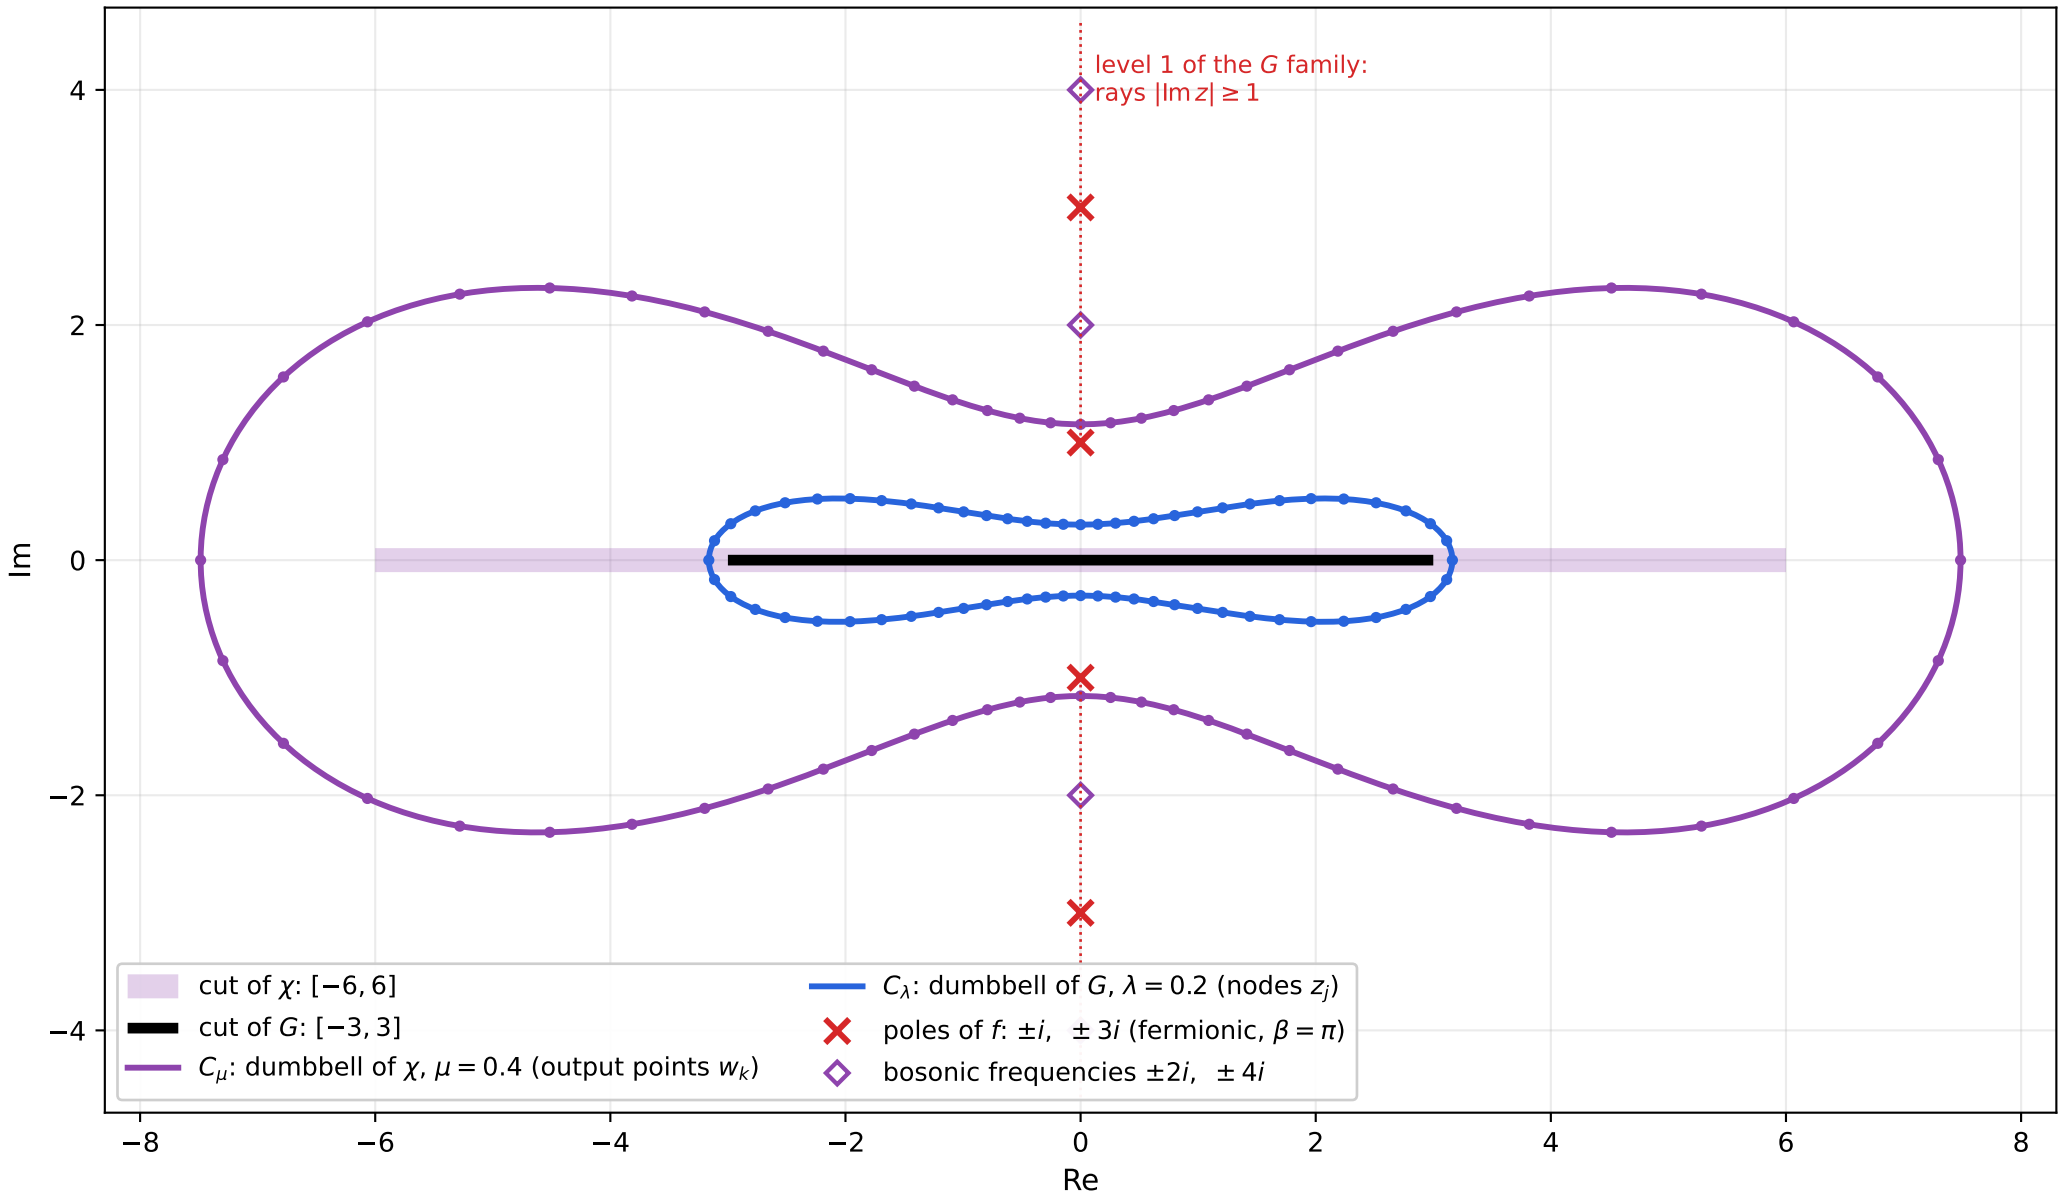
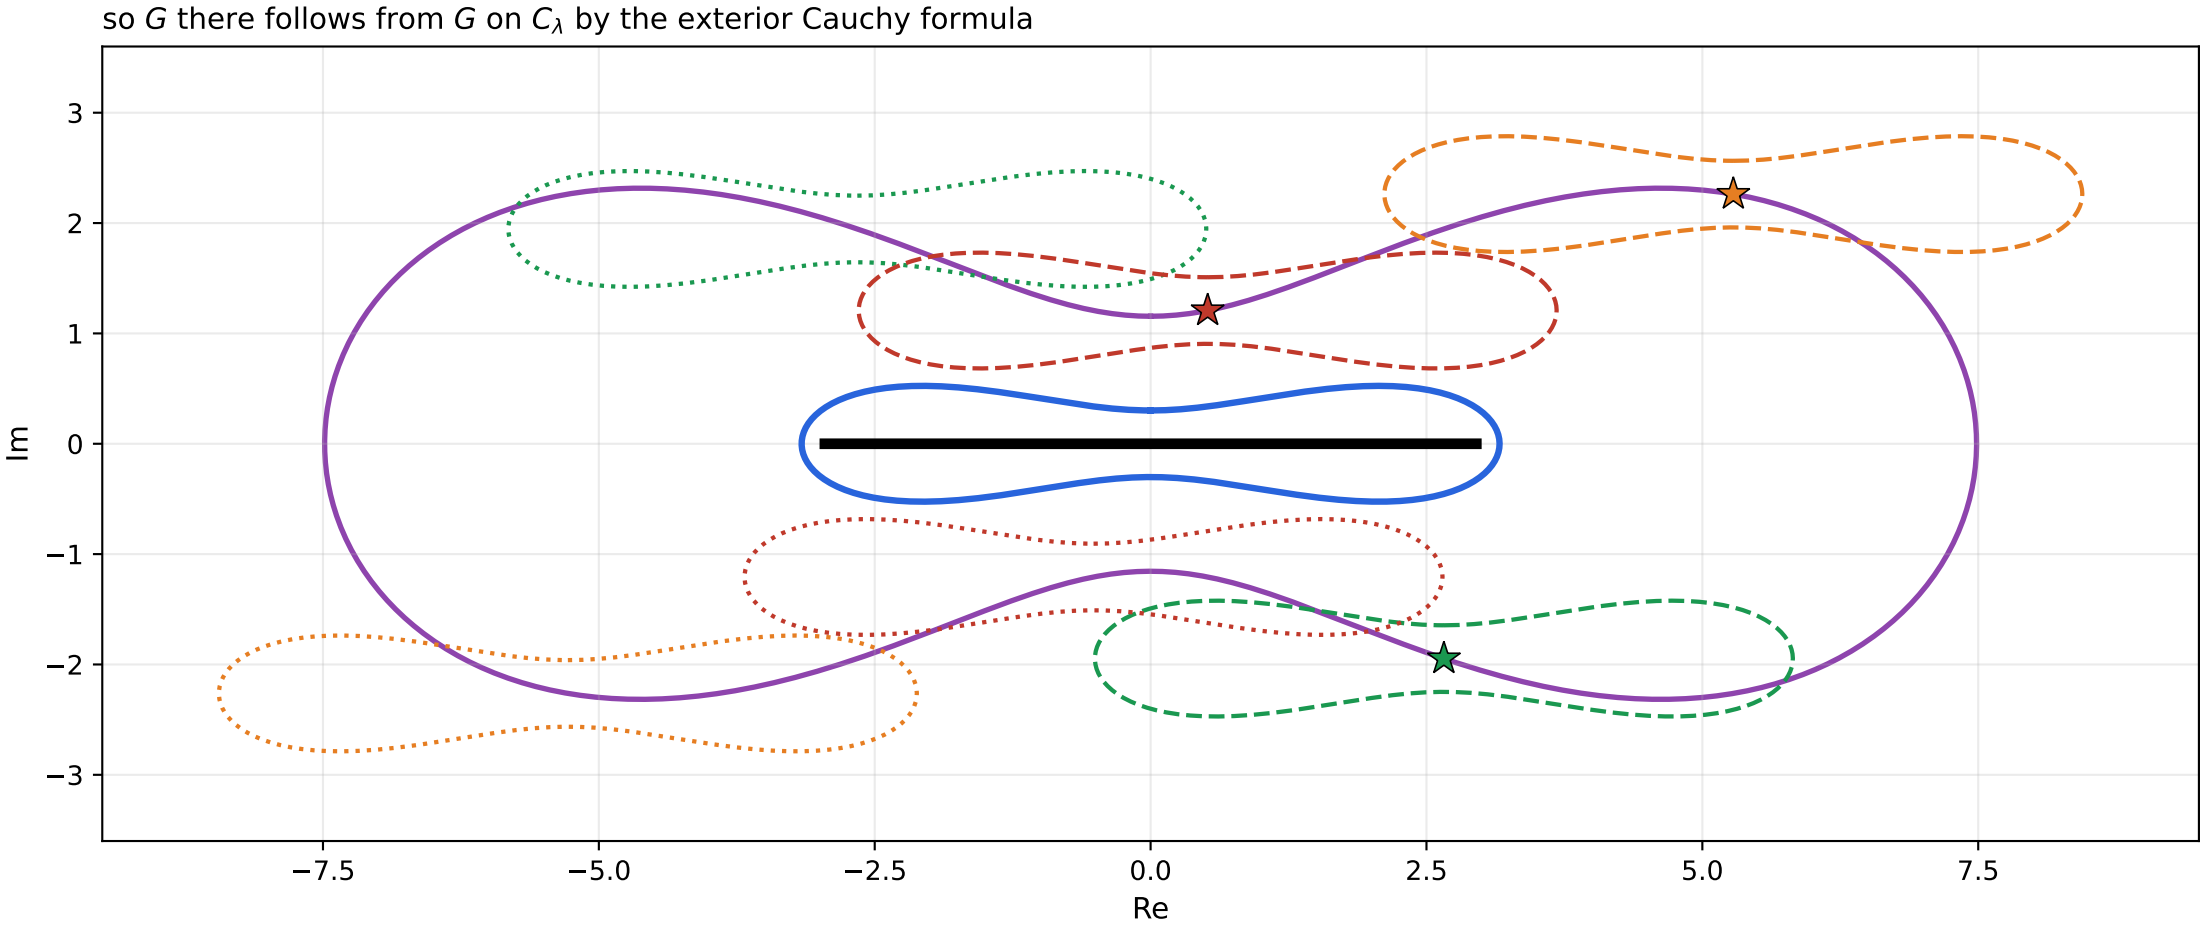
(a) The two contours. G is stored on C_λ (512 nodes $z_j = \omega_\lambda(\phi_j)$, every 8th drawn); χ is computed on C_μ (512 points $w_k = 2\,\omega_\mu(\phi_k)$)





(b) The bubble needs G at $z_j \pm w_k$, i.e. on the copies $C_\lambda \pm w_k$, for the points w_k on C_μ (purple).
The copies avoid the cut of G and stay outside C_λ: their lowest level is $\lambda'_{\min} = 0.237 > \lambda = 0.2$ (forward-safe),
so G there follows from G on C_λ by the exterior Cauchy formula
